

Logical Flow of Tracked Changes

Local Repository: (.git folder)

All of your staged files, committed files, history of changes and snapshots are managed by git and contained within the .git folder.

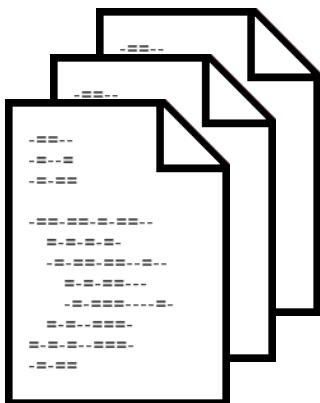

`git commit -m "message"`

Staging Area:

The staging area is a logical area where you add all the changed files you want to include in the next commit. This area exists within the .git folder, but it's easier to think of it as a logical location between the working directory and the local repository

`git add <filename>`

Source Files:

You edit the source files you need for the next feature or update. When you're ready to add these files to the staging area, you will use the "git add" command.
